Shared Memory Programming with OpenMP

Ramses van Zon SciNet HPC Consortium University of Toronto

May 8, 2013

Outline

1. The OpenMP model: threads, memory, and performance

Hands On 1: Parallelizing daxpy

2. Reductions and load balancing

Hands-On 2: Mandelbrot set

3. Advanced OpenMP features

Assumed knowledge: C and/or Fortran scientific programming; experience editing and compiling code in a Linux environment.

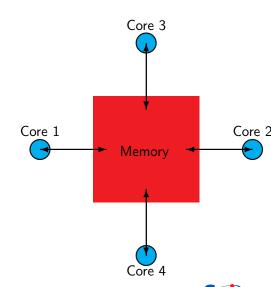

Shared Memory

One large bank of memory, different computing cores acting on it. All 'see' same data.

Any coordination done through memory

Could use message passing, but no need.

Each code is assigned a thread of execution of a single program that acts on the data.

- ► For shared memory systems.
- Add parallelism to functioning serial code.
- http://openmp.org

The seminar is free. Allocation is on a first come, first served basis, as we are limited

capacity. Please register separately for any session you intend to participate. Go to:

Discuss

- For shared memory systems.
- Add parallelism to functioning serial code.
- http://openmp.org
- Compiler, run-time env does most of the work
- But we have to tell it how to use variables, where to run in parallel, . . .
- Mark parallel regions.
- Works by adding compiler directives to code.

 Invisible to non-openmp compilers.

Incremental parallelism

Compiler directives-based parallization

- OpenMP
- OpenACC
 - ▶ Does for GPU programming what OpenMP does for threading
 - Alternative to CUDA (but no free implementation yet).
 - ► Similar incremental parallelism as for OpenMP
 - Differs from OpenMP in that memory needs to be copied over
- Intel MIC Compilers
 - MIC, or more proper, the Xeon Phi, is an Intel multicore co-processor with its own memory.
 - ► Host/Device setup is similar to the CPU, but internal architecture is shared-memory x86.
 - ▶ With the Intel compilers (v13+) you can use compiler directives for offloading to the MIC as well.
- Compiler-specific vectorization hints

Much of this will be folded into OpenMP 4.

OpenMP basic operations

In code:

- ▶ In C, you add lines starting with #pragma omp. This parallelizes the subsequent code block.
- ▶ In Fortran, you add lines starting with !\$omp.
 An !\$omp end ... is needed to close the parallel region.
- ► These lines are skipped (for C, sometimes with a warning) by compilers that do not support OpenMP.

OpenMP basic operations

In code:

- ▶ In C, you add lines starting with #pragma omp. This parallelizes the subsequent code block.
- ▶ In Fortran, you add lines starting with !\$omp.
 An !\$omp end ... is needed to close the parallel region.
- These lines are skipped (for C, sometimes with a warning) by compilers that do not support OpenMP.

When compiling:

► To turn on OpenMP support in gcc and gfortran, add the -fopenmp flag to the compilation (and link!) commands.

OpenMP basic operations

In code:

- ▶ In C, you add lines starting with #pragma omp. This parallelizes the subsequent code block.
- ▶ In Fortran, you add lines starting with !\$omp.
 An !\$omp end ... is needed to close the parallel region.
- These lines are skipped (for C, sometimes with a warning) by compilers that do not support OpenMP.

When compiling:

► To turn on OpenMP support in gcc and gfortran, add the -fopenmp flag to the compilation (and link!) commands.

When running:

► The environment variable OMP_NUM_THREADS determines how many threads will be started in an OpenMP parallel block

(

1_helloworld/omp-hello-world.c

```
#include <stdio.h>
#include <omp.h>
int main() {
  printf("At start of program\n");
  #pragma omp parallel
  {
    printf("Hello world from thread %d!\n", omp_get_thread_num());
  }
}
```

Fortran:

1_helloworld/omp-hello-world-f.f90

```
program omp_hello_world
use omp_lib
implicit none
print *, 'At start of program'
!somp parallel
   print *, 'Hello world from thread ', omp_get_thread_num(), '!'
!somp end parallel
end program omp_hello_world
```

Getting started with this code

All sample code is on the usb drive, but to do this on the gpc:

```
$ ssh USER@login.scinet.utoronto.ca -X #get into SciNet
$ ssh gpc01 -X #get on the GPC
$ qsub -l nodes=1:ppn=8,walltime=4:00:00 -I -X
... #get your own compute node
$ cd $SCRATCH
$ cp -r /scinet/course/ss2013 .
$ cd ss2013/HPC107_openmp/code
$ source setup
$ cd 1_helloworld
```

OpenMP example

```
$ gcc -fopenmp -o omp-hello-world omp-hello-world.c
or
$ gfortran -fopenmp -o omp-hello-world-f \
   omp-hello-world-f.f90
or
$ make omp-hello-world omp-hello-world-f
$ export OMP_NUM_THREADS=8
$ ./omp-hello-world
$ export OMP_NUM_THREADS=1
$ ./omp-hello-world
$ export OMP_NUM_THREADS=32
$ ./omp-hello-world
```

Let's see what happens...

OpenMP example

```
$ gcc -o omp-hello-world omp-hello-world.c -fopenmp
    $ export OMP_NUM_THREADS=8
    $ ./omp-hello-world
    At start of program
    Hello, world, from thread 0!
    Hello, world, from thread 6!
    Hello, world, from thread 5!
    Hello, world, from thread 4!
    Hello, world, from thread 2!
    Hello, world, from thread 1!
    Hello, world, from thread 7!
    Hello, world, from thread 3!
    $ export OMP_NUM_THREADS=1
    $ ./omp-hello-world
    At start of program
    Hello, world, from thread 0!
    $ export OMP_NUM_THREADS=32
    $ ./omp-hello-world
    At start of program
    Hello, world, from thread 11!
    Hello, world, from thread 1!
10/41 - Hello, world, from thread 16!
```

```
$ gcc -o omp-hello-world omp-hello-world.
                             $ export OMP_NUM_THREADS=8
                             $ ./omp-hello-world
                             At start of program
                             Hello, world, from thread 0!
                             Hello, world, from thread 6!
                             Hello, world, from thread 5!
OMP_NUM_THREADS
                             Hello, world, from thread 4!
  threads were launched.
                             Hello, world, from thread 2!
                             Hello, world, from thread 1!
Each prints "Hello, world
                             Hello, world, from thread 7!
  . . . " ;
                             Hello, world, from thread 3!
                             $ export OMP_NUM_THREADS=1
In seemingly random order.
                             $ ./omp-hello-world
Only one "At start of
                             At start of program
  program".
                             Hello, world, from thread 0!
                             $ export OMP_NUM_THREADS=32
                             $ ./omp-hello-world
                             At start of program
                             Hello, world, from thread 11!
```

Hello, world, from thread 1! Hello, world, from thread 16!

```
#include <stdio.h>
#include <omp.h>
int main() {
  printf("At start of program\n");
  #pragma omp parallel
  {
    printf("Hello world from thread %d!\n", omp_get_thread_num());
    }
}
```

```
program omp_hello_world
use omp_lib
implicit none
print *, 'At start of program'
!Somp parallel
  print *, 'Hello world from thread ', omp_get_thread_num(), '!'
!Somp end parallel
end program omp_hello_world
```

```
#include <stdio.h>
#include <omp.h>
int main() {
  printf("At start of program\n");
  #pragma omp parallel
  {
    printf("Hello world from thread %d!\n", omp_get_thread_num());
  }
}
Program starts normally (single thread)
```

```
program omp_hello_world
use omp_lib
implicit none
print *, 'At start of program'
!somp parallel
  print *, 'Hello world from thread ', omp_get_thread_num(), '!'
!somp end parallel
end program omp_hello_world
```

```
#include <stdio.h>
#include <omp.h>
int main() {
 printf("At start of program\n");
 #pragma omp parallel
   printf("Hello world from thread %d!\n", omp_get_thread_num());
                                   At start of parallel section, launching
                                    OMP NUM THREADS threads.
                                    Each executes the same code!
program omp_hello_world
use omp_lib
implicit none
print *, 'At start of program'
!$omp parallel
 print *, 'Hello world from thread ', omp_get_thread_num(), '!'
!somp end parallel
end program omp_hello_world
```

```
program omp_hello_world
use omp_lib
implicit none
print *, 'At start of program'
!somp parallel
  print *, 'Hello world from thread ', omp_get_thread_num(), '!'
!somp end parallel
end program omp_hello_world
```

```
program omp_hello_world
use omp_lib
implicit none
print *, 'At start of program'
!somp parallel
    print *, 'Hello world from thread ', omp_get_thread_num(), '!'
!somp end parallel
end program omp_hello_world
```

By including omp.h, you get a smal number of omp functions:

```
omp_get_thread_num()
```

- omp_get_num_threads()

1_helloworld/omp-hello-world2.c

omp_get_num_threads() called by all threads.

1_helloworld/omp-hello-world3.c

```
#include <stdio.h>
#include <omp.h>
int main() {
  printf("At start of program\n");
  #pragma omp parallel
  {
    printf("Hello world from thread %d!\n",
        omp_get_thread_num());
  }
  printf("There were %d threads.\n", omp_get_num_threads());
}
```

What do you think, will this work?

1_helloworld/omp-hello-world3.c

```
#include <stdio.h>
#include <omp.h>
int main() {
  printf("At start of program\n");
  #pragma omp parallel
  {
    printf("Hello world from thread %d!\n",
        omp_get_thread_num());
  }
  printf("There were %d threads.\n", omp_get_num_threads());
}
```

What do you think, will this work?

No:

Says 1 thread only!

1_helloworld/omp-hello-world3.c

What do you think, will this work?

No:

Says 1 thread only!

Why?

Because that is true outside the parallel region!

Need to get the value from the parallel region somehow.

```
#include <stdio.h>
#include <omp.h>
int main() {
 int mythread, nthreads;
 #pragma omp parallel default(none) shared(nthreads) private(mythread)
   mythread = omp_get_thread_num();
   if (mythread == 0)
     nthreads = omp_get_num_threads();
 printf("There were %d threads.\n", nthreads);
```

```
#include <stdio.h>
                                     Variable declarations
#include <omp.h>
                                     How used in parallel region
int main() {
 int mythread, nthreads;
 #pragma omp parallel default(none) shared(nthreads) private(mythread)
   mythread = omp_get_thread_num();
   if (mythread == 0)
     nthreads = omp_get_num_threads();
 printf("There were %d threads.\n", nthreads);
```

```
#include <stdio.h>
                                     Variable declarations
#include <omp.h>
                                     How used in parallel region
int main() {
 int mythread, nthreads:
 #pragma omp parallel default(none) shared(nthreads) private(mythread)
   mythread = omp_get_thread_num();
   if (mythread == 0)
     nthreads = omp_get_num_threads();
 printf("There were %d threads.\n", nthreads);
```

- default(none) can save you hours of debugging!
- shared: each thread sees it and can modify (be careful!).
 Preserves value
- private: each thread gets it own copy, invisible for others Initial and final value undefined!
 - (Advanced: firstprivate, lastprivate copy in/out.)

```
#include <stdio.h>
#include <omp.h>
int main() {
 int mythread, nthreads;
 #pragma omp parallel default(none) shared(nthreads) private(mythread)
   mythread = omp_get_thread_num();
   if (mythread == 0)
     nthreads = omp_get_num_threads();
 printf("There were %d threads.\n", nthreads):
```

- Program runs, launches threads.
- Each thread gets copy of mythread.
- Only thread 0 writes to nthreads.

```
#include <stdio.h>
#include <omp.h>
int main() {
 int mythread, nthreads;
 #pragma omp parallel default(none) shared(nthreads) private(mythread)
   mythread = omp_get_thread_num();
   if (mythread == 0)
     nthreads = omp_get_num_threads();
 printf("There were %d threads.\n", nthreads):
```

- Program runs, launches threads.
- Each thread gets copy of mythread.
- Only thread 0 writes to nthreads.
- Good idea to declare mythread locally! (avoids many bugs)

```
#include <stdio.h>
#include <omp.h>
int main() {
 int nthreads:
 #pragma omp parallel default(none) shared(nthreads)
   int mythread = omp_get_thread_num();
   if (mythread == 0)
     nthreads = omp_get_num_threads();
 printf("There were %d threads.\n", nthreads);
```

- Program runs, launches threads.
- ► Each thread gets copy of mythread.
- Only thread 0 writes to nthreads.
- Good idea to declare mythread locally! (avoids many bugs)
- ▶ 1_helloworld/omp-hello-world4.c

Variables in OpenMP - Fortran version

1_helloworld/omp-hello-world4-f.f90

```
program omp_vars
use omp_lib
implicit none
integer :: mythread, nthreads
!$omp parallel default(none) private(mythread) shared(nthreads)
 mythread = omp_get_thread_num()
 if (mythread == 0) then
   nthreads = omp_get_num_threads()
 endif
!somp end parallel
print *,'Number of threads was ', nthreads, '.'
end program omp_vars
```

Single Execution in OpenMP

1_helloworld/omp-hello-world4.c

```
#include <stdio.h>
#include <omp.h>
int main() {
 int nthreads:
 #pragma omp parallel default(none) shared(nthreads)
   int mythread = omp_get_thread_num();
   if (mythread == 0)
     nthreads = omp_get_num_threads();
 printf("There were %d threads.\n", nthreads):
```

- ► Do we care that it's thread 0 in particular that updates nthreads?
- Often, we just want the first thread to go through, do not care which one.

Single Execution in OpenMP

```
#include <stdio.h> // 1_helloworld/omp-hello-world5.c
#include <omp.h>
int main() {
  int nthreads;
  #pragma omp parallel default(none) shared(nthreads)
  #pragma omp single
   nthreads = omp_get_num_threads();
  printf("There were %d threads.\n", nthreads);
}
```

```
program omp_vars
use omp_lib
implicit none
integer :: nthreads
!somp parallel default(none) shared(nthreads)
!somp single
   nthreads = omp_get_num_threads()
!somp end single
!somp end parallel
print *,'Number of threads was ', nthreads, '.'
end program omp_vars
```

Loops in OpenMP

Consider following openmp programs with a loop.

Loops in OpenMP

Consider following openmp programs with a loop.

```
#include <stdio.h>
                                        program omp_loop
#include <omp.h>
                                        use omp_lib
int main() {
                                        implicit none
                                        integer :: i, mythread
 int i, mythread;
 #pragma omp parallel default(none)\
                                        !somp parallel default(none) &
  XXXX(i) private(mythread)
                                        !$omp XXXX(i) private(mythread)
                                          mythread = omp_get_thread_num()
   mythread = omp_get_thread_num();
                                          do i=1,16
   for (i=0; i<16; i++)
                                            print *, 'thread ', mythread, &
     printf("Thread %d gets i=%d\n",
                                                     ' gets i='. i
            mythread, i);
                                          enddo
                                        !somp end parallel
                                        end program omp_loop
```

Loops in OpenMP

Consider following openmp programs with a loop.

```
#include <stdio.h>
                                        program omp_loop
#include <omp.h>
                                        use omp_lib
int main() {
                                        implicit none
                                        integer :: i, mythread
 int i, mythread;
 #pragma omp parallel default(none)\
                                         !somp parallel default(none) &
  XXXX(i) private(mythread)
                                         !$omp XXXX(i) private(mythread)
                                          mythread = omp_get_thread_num()
   mythread = omp_get_thread_num();
                                          do i=1,16
   for (i=0; i<16; i++)
                                            print *, 'thread ', mythread, &
     printf("Thread %d gets i=%d\n",
                                                     ' gets i='. i
            mythread, i);
                                          enddo
                                         !somp end parallel
                                        end program omp_loop
```

How should we declare i, as private or as shared?

Loops in OpenMP

Consider following openmp programs with a loop.

```
#include <stdio.h>
                                        program omp_loop
#include <omp.h>
                                        use omp_lib
int main() {
                                        implicit none
                                        integer :: i, mythread
 int i, mythread;
 #pragma omp parallel default(none)\
                                        !somp parallel default(none) &
  XXXX(i) private(mythread)
                                        !$omp XXXX(i) private(mythread)
                                          mythread = omp_get_thread_num()
   mythread = omp_get_thread_num();
                                          do i=1.16
   for (i=0; i<16; i++)
                                            print *, 'thread ', mythread, &
     printf("Thread %d gets i=%d\n",
                                                     ' gets i=', i
            mythread, i);
                                          enddo
                                        !somp end parallel
                                        end program omp_loop
```

How should we declare i, as private or as shared? What would you imagine this does when run with e.g. OMP_NUM_THREADS=8?

Loops in OpenMP

Consider following openmp programs with a loop.

```
#include <stdio.h>
                                        program omp_loop
#include <omp.h>
                                        use omp_lib
int main() {
                                        implicit none
                                        integer :: i, mythread
 int i, mythread;
 #pragma omp parallel default(none)\
                                        !somp parallel default(none) &
  XXXX(i) private(mythread)
                                        !$omp XXXX(i) private(mythread)
                                          mythread = omp_get_thread_num()
   mythread = omp_get_thread_num();
                                          do i=1.16
   for (i=0; i<16; i++)
                                            print *, 'thread ', mythread, &
     printf("Thread %d gets i=%d\n",
                                                     ' gets i=', i
            mythread, i);
                                          enddo
                                        !somp end parallel
                                        end program omp_loop
```

2_loop/omp-loop.c

2_loop/omp-loop-f.f90

How should we declare i, as private or as shared? What would you imagine this does when run with e.g. OMP_NUM_THREADS=8?

Worksharing constructs in OpenMP

- We don't generally want tasks to do exactly the same thing.
- Want to partition a problem into pieces, each thread works on a piece.
- ▶ Most scientific programming full of work-heavy loops.
- OpenMP has a work-sharing construct: omp for (or omp do).

Worksharing constructs in OpenMP

- ▶ We don't generally want tasks to do exactly the same thing.
- Want to partition a problem into pieces, each thread works on a piece.
- ▶ Most scientific programming full of work-heavy loops.
- ▶ OpenMP has a work-sharing construct: omp for (or omp do).

```
#include <stdio.h>
#include <omp.h>
int main() {
 int i, mythread;
 #pragma omp parallel default(none) XXXX(i) private(mythread)
   mythread = omp_get_thread_num();
   #pragma omp for
   for (i=0; i<16; i++)
     printf("Thread %d gets i=%d\n",mythread,i);
```

Fortran version

```
program omp_loop
use omp_lib
implicit none
integer :: i, mythread
!$omp parallel default(none) XXXX(i) XXXX(mythread)
 mythread = omp_get_thread_num()
  !somp do
 do i=1.16
   print *, 'thread ', mythread, ' gets i=', i
 enddo
  !somp end do
!somp end parallel
end program omp_loop
```

2_loop/omp-loop2-f.f90

Worksharing constructs in OpenMP

- omp for/omp do construct breaks up the iterations by thread.
- If doesn't divide evenly, does the best it can.
- Allows easy breaking up of work!
- Advanced: can break up work of arbitrary blocks of code with omp task construct.

```
$ ./omp-loop2
thread 3 gets i=6
thread 3 gets i=7
thread 4 gets i=8
thread 4 gets i=9
thread 5 gets i=10
thread 5 gets i=11
thread 6 gets i=12
thread 6 gets i=13
thread 1 gets i=2
thread 1 gets i=3
thread 0 gets i=0
thread 0 gets i=1
thread 2 gets i=4
thread 2 gets i=5
thread 7 gets i=14
thread 7 gets i=15
```

Less trivial example: DAXPY

- multiply a vector by a scalar, add a vector.
- (a X plus Y, in double precision)
- Given serial implementation, will start adding OpenMP

$$z = ax + y$$

- daxpy.c or daxpy.f90
- cd 3_daxpy; make daxpy or make daxpy-f

Warning

This is a common linear algebra construct that you really shouldn't implement yourself. Various so-called BLAS implementations will do a much better job than you. But good for illustration.

```
#include <stdio.h>
#include "pca_utils.h"
void daxpy(int n, double a, double *x, double *y, double *z) {
 for (int i=0; i<n; i++) {</pre>
   x[i] = (double)i*(double)i;
   y[i] = ((double)i+1.)*((double)i-1.);
 }
 for (int i=0; i<n; i++)</pre>
   z[i] += a * x[i] + y[i];
int main() {
 int n=1e7;
 double *x = vector(n);
 double *y = vector(n);
 double *z = vector(n):

pute • calcul

HANDS-ON 1:

Parallelize daxpy with OpenMP: Edit the files omp-daxpy.c or omp-daxpy.f90. Compile with make Also do the scaling analysis!

```
void daxpy(int n, double a, double *x, double *y, double *z) {
 #pragma omp parallel default(none) shared(n,x,y,a,z) private(i)
   #pragma omp for
   for (int i=0; i<n; i++) {</pre>
     x[i] = (double)i*(double)i;
     y[i] = ((double)i+1.)*((double)i-1.);
   }
   #pragma omp for
   for (int i=0; i<n; i++)</pre>
     z[i] += a * x[i] + y[i];
!$omp parallel default(none) private(i) shared(a,x,b,y,z)
!somp do
do i=1.n
 x(i) = (i)*(i)
 y(i) = (i+1.)*(i-1.)
enddo
!somp do
do i=1.n
 z(i) = a*x(i) + y(i)
enddo
!somp end parallel
```

```

```

Dot Product

- Dot product of two vectors
- Implement this, first serially, then with OpenMP
- ndot.c or ndot.f90
- make ndot or make fndot
- ► Tells time, answer, correct answer.

$$n = \vec{x} \cdot \vec{y}$$
$$= \sum_{i} x_{i} y_{i}$$

\$./ndot
Dot product is 3.3333e+20
(vs 3.3333e+20) for n=10000000.
Took 4.9254e-02 seconds.

Dot Product - serial

```
#include <stdio.h>
#include "pca_utils.h"
double ndot(int n, double *x, double *y){
 double tot=0:
 for (int i=0; i<n; i++)</pre>
  tot += x[i] * y[i];
 return tot;
int main() {
 int n=1e7:
 double *x = vector(n), *y = vector(n);
 for (int i=0; i<n; i++)</pre>
   x[i] = y[i] = i;
 double nn=n-1;
 double ans=nn*(nn+1)*(2*nn+1)/6.0:
 pca_time tt;
 tick(&tt):
 double dot=ndot(n,x,y);

   dot. ans. n. tocksilent(&tt)):
```

Towards A Parallel Dot Product

- We could clearly parallelize the loop.
- We need the sum from everybody.
- We could make tot shared, then all threads can add to it.

```
double ndot(int n, double *x, double *y){
  double tot=0;
  #pragma omp parallel for de-
  fault(none) shared(tot,n,x,y)
  for (int i=0; i<n; i++)
    tot += x[i] * y[i];
  return tot;
}</pre>
```

```
$ make omp_ndot_race
$ export OMP_NUM_THREADS=8
$ ./omp_ndot_race
Dot product is 1.1290e+20
(vs 3.3333e+20) for n=10000000.
Took 5.2628e-02 secs.
```

- Classical parallel bug.
- Multiple writers to some shared resource.
- Can be very subtle, and only appear intermittently.
- Your program can have a bug but not display any symptoms for small runs!
- Primarily a problem with shared memory.

 $\begin{array}{ccc} & \text{tot} = 0 \\ \textbf{Thread 0:} & \textbf{Thread 1:} \\ \textbf{add 1} & \textbf{add 2} \end{array}$

tot = 2		

tot = 2

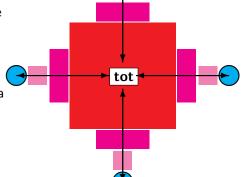

Race Condition - why it's slow

 Multiple cores repeatedly trying to read, access, store same variable in memory.

Not (such) a problem for constants (read only); but a big problem for writing.

Sections of arrays – better.

OpenMP critical construct

- Defines a critical region.
- Only one thread can be operating within this region at a time.
- Keeps modifications to shared resources safe.
- #pragma omp critical
- !somp critical
 !somp end critical

```
$ make omp_ndot_critical
$ export OMP_NUM_THREADS=8
$ ./omp_ndot_critical
Dot product is 3.3333e+20
(vs 3.3333e+20) for n=10000000.
Took 5.1377e+00 secs.
```

Correct, but 100x slower than serial version!

OpenMP atomic construct

- Most hardware has support for atomic instructions (indivisible so cannot get interrupted)
- Small subset, but load/add/stor usually one.
- Not as general as critical
- Much lower overhead.
- ▶ #pragma omp atomic
- !somp atomic

```
double ndot(int n, double *x,
double *y){
  double tot=0;
  #pragma omp parallel for \
  default(none) shared(tot,n,x,y)
  for (int i=0; i<n; i++)
    #pragma omp atomic
    tot += x[i] * y[i];
  return tot;
}</pre>
```

```
$ make omp_ndot_atomic $ export
OMP_NUM_THREADS=8
$ ./omp_ndot_atomic
Dot product is 3.3333e+20
(vs 3.3333e+20) for n=10000000.
Took 8.5156e-01 secs.
```

Correct, and better – only 16x slower than serial.

How should we fix the slowdown?

- Local sums.
- Each processor sums its local values (10⁷/P additions).
- And then sums to tot (only P additions with critical or atomic...

$$\begin{split} n &= \vec{x} \cdot \vec{y} \\ &= \sum_i x_i \ y_i \\ &= \sum_p \left(\sum_i x_i \ y_i \right) \end{split}$$

Local variables

```
tot = 0;
#pragma omp parallel shared(x,y,n,tot)
{
  int mytot = 0;
  #pragma omp for
  for (int i=0; i<n; i++)
    mytot += x[i]*y[i];
  #pragma omp atomic
  tot += mytot;
}</pre>
```

```
ndot = 0.
!$omp parallel shared(x,y,n,ndot) &
!$omp private(i,mytot)
mytot = 0.
!$omp do
do i=1,n
  mytot = mytot + x(i)*y(i)
enddo
!$omp atomic
ndot = ndot + mytot
!$omp end parallel
```

```
$ export OMP_NUM_THREADS=8
$ ./omp_ndot_local
```

Dot product is 3.3333e+20 (vs 3.3333e+20) for n=10000000.

Took 1.7902-02 seconds.

Now we're talking! 2.77x faster.

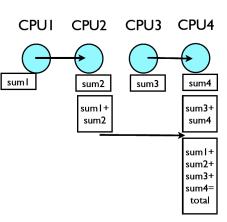

OpenMP Reduction Operations

This is such a common operation, this is something built into OpenMP to handle it.

- ► Can support several types of operations: - + * ...
- omp_ndot_reduction.c, fomp_ndot_reduction.f90

OpenMP Reduction Operations

```
tot = 0;
#pragma omp parallel \
shared(x,y,n) reduction(+:tot)
{
    #pragma omp for
    for (int i=0; i<n; i++)
        tot += x[i]*y[i];
}</pre>
```

```
ndot = 0.
!$omp parallel shared(x,y,n) &
!$omp private(i) reduction(+:ndot)
!$omp do
do i=1,n
  ndot = ndot + x(i)*y(i)
enddo
!$omp end parallel
```

```
$ export OMP_NUM_THREADS=8
$ ./omp_ndot_local
Dot product is 3.3333e+20
(vs 3.3333e+20) for n=10000000.
Took 1.8134-02 seconds.
```

Same speed, simpler code!

OpenMP Reduction Operations

```
tot = 0;
#pragma omp parallel for \
shared(x,y,n) reduction(+:tot)
for (int i=0; i<n; i++)
  tot += x[i]*y[i];</pre>
```

```
ndot = 0.
!somp parallel do shared(x,y,n) &
!somp private(i) reduction(+:ndot)
do i=1,n
  ndot = ndot + x(i)*y(i)
enddo
!somp end parallel
```

```
$ export OMP_NUM_THREADS=8
$ ./omp_ndot_local
Dot product is 3.3333e+20
(vs 3.3333e+20) for n=10000000.
Took 1.8928e-02 seconds.
```

Same speed, simpler code!

Performance

- ▶ We threw in 8 cores, got a factor of 3 speedup. Why?
- Often we are limited not by CPU power but by how quickly we can feed CPUs.
- ► For this problem, we had 107 long vectors, with 2 numbers 8 bytes long flowing through in 0.036 seconds.
- ► Combined bandwidth from main memory was 4.3 GB/s. Not far off of what we could hope for on this architecture.
- ➤ One of the keys to good OpenMP performance is using data when we have it in cache. Complicated functions: easy. Low work-per-element (dot product, FFT): hard.

Memory Access

- Processors work on local bits of memory in their cache.
- Cache is small and fast. Main memory is big, but slow.
- There is a large latency in getting things from main memory
 — often hundreds of clock cycles. The fewer times we access main memory, the faster we will go.
- Computers bring in chunks of memory at a time. If you access data in contiguous memory chunks, much of it may already be in cache. Always try to do this - serial or parallel.
- ▶ C last index is rapidly varying. Fortran first index.

Memory Access

- ► Memory access is important for serial programs, but can become particularly important in OpenMP
- ▶ There is typically a limited bandwidth to main memory. If it has to be shared 2, 4, or 8 ways, it becomes especially critical to access it sensibly.
- ▶ Note on shared variables in OpenMP: If you aren't changing them, the compiler can copy the shared variable to local cache and no performance hit. Modifying shared variables is expensive we have already seen this with the dot product.

Load Balancing in OpenMP

Load Balancing in OpenMP

- So far every iteration of the loop had the same amount of work.
- Not always the case
- Sometimes cannot predict beforehand how unbalanced the problem is

OpenMP has work sharing construct that allow you do statically or dynamically balance the load.

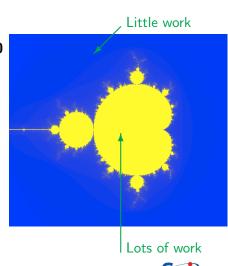

Example - Mandelbrot Set

- Mandelbrot set simple example of non-balanced problem.
- ▶ Defined as complex points a where $|b_{\infty}|$ finite, with $b_0 = 0$ and $b_{n+1} = b_n^2 + a$. If $|b_n| > 2$, point diverges.
- Calculation:
 - pick some nmax
 - ▶ iterate for each point a, see if crosses 2.
 - ▶ Plot **n** or **nmax** as colour.

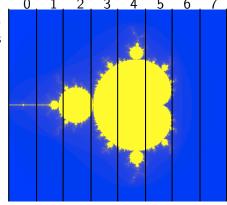

Outside of set, points diverge quickly (2-3 steps). Inside, we have to do lots of work (1000s steps).

► make mandel; ./mandel

First OpenMP Mandelbrot Set

- ▶ Default work sharing breaks N iterations into ∑N/nthreads contiguous chunks and assigns them to threads.
- But now threads 7,6,5 will be done and sitting idle while threads 3 and 4 work alone...
- Inefficient use of resources.

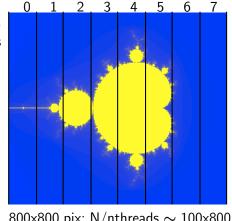

800x800 pix; N/nthreads \sim 100x800

First OpenMP Mandelbrot Set

- Default work sharing breaks N iterations into $\sum N/n$ threads contiguous chunks and assigns them to threads.
- ▶ But now threads 7,6,5 will be done and sitting idle while threads 3 and 4 work alone...
- Inefficient use of resources.

Serial	0.63s
Nthreads=8	0.29s
Speedup	2.2x
Efficiency	27%

800x800 pix; N/nthreads $\sim 100x800$

Scheduling constructs in OpenMP

- Default: each thread gets a big consecutive chunk of the loop. Often better to give each thread many smaller interleaved chunks.
- ► Can add schedule clause to omp for to change work sharing.
- We can decide either at compile-time (static schedule) or run-time (dynamic schedule) how work will be split.
- #pragma omp for schedule(static, m) gives m consecutive loop elements to each thread instead of a big chunk.
- With schedule(dynamic, m), each thread will work through m loop elements, then go to the OpenMP run-time system and ask for more.
- ► Load balancing (possibly) better with dynamic, but larger overhead than with static.

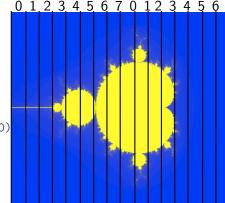

HANDS-ON 2:

Use the OpenMP scheduling constructs to try and make mandel more efficient.

Second Try OpenMP Mandelbrot Set

- ► Can change the chunk size different from ~ N/nthreads
- ► In this case, more columns work distributed a bit better.
- Now, for instance, chunk size 50, and thread 7 gets both a big work chunk and a little one:

800x800 pix; each threads: 50x800

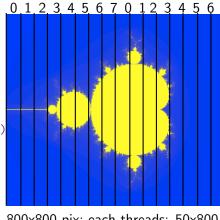

Second Try OpenMP Mandelbrot Set

- Can change the chunk size different from $\sim N/n$ threads
- ▶ In this case, more columns work distributed a bit better.
- Now, for instance, chunk size 50, and thread 7 gets both a big work chunk and a little one:

#pragma omp for schedule(static,50) or

!somp do schedule(static,50)

Serial	0.63s
Nthreads=8	0.15s
Speedup	4.2x
Efficiency	52%

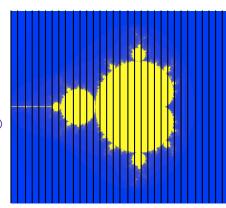

800x800 pix; each threads: 50x800

Third Try: Schedule dynamic

- Break up into many pieces and hand them to threads when they are ready.
- Dynamic scheduling.
- Increases overhead, decreases idling threads.
- Can also choose chunk size.

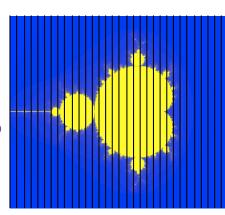

Third Try: Schedule dynamic

- Break up into many pieces and hand them to threads when they are ready.
- Dynamic scheduling.
- Increases overhead, decreases idling threads.
- Can also choose chunk size.

!somp do schedule(dynamic)

Serial	0.63s
Nthreads=8	0.10s
Speedup	6.3x
Efficiency	79%

Tuning

- schedule(static) (default) or schedule(dynamic) are good starting points.
- ➤ To get best performance in badly imbalanced problems, may have to play with chuck size; depends on your problem and on hardware.

(static,4)	(dynamic,16)
0.084s	0.099s
7/6x	6.4x
95%	79%

Two level loops

Why?

In scientific code, we usually have nested loops were all the work is.

Almost without exception, want the pragma omp on the outside-most loop.

```
#pragma omp for schedule(static,4)
for (int i=0;i<npix;i++)
  for (int j=0;j<npix;j++){
    double
    x=((double)i)/((double)npix);
    double
    y=((double)j)/((double)npix);
    double complex a=x+I*y;
    mymap[i][j]=how_many_iter_real(a,maxiter)}</pre>
```

Summary

- Start a parallel region: #pragma omp parallel shared() private() default()
- Parallelize a loop: #pragma omp for schedule(static/dynamic, chunk)
- Mark off a region only one thread can be in at a time: #pragma omp critical
- Safely update a single memory location: #pragma omp atomic
- In a parallel region, have only one process do something: #pragma omp single

Style Points

- ▶ If a variable is a private temporary variable inside a parallel region, try declaring it inside the region. Makes parallel region easier to specify, and can prevent bugs.
- OpenMP supports reduction and initialization clauses. These are never necessary to use, but are convenient and can streamline code.
- You have seen how to find out how many threads exist, etc. However, in none of our examples did we use that info. If you think you need to know how many threads you have, you may well be doing something wrong (with some notable exceptions such as complex reduction). Using locally declared variables, and critical regions most likely will do everything you need.

Further OpenMP Features

A Few More Directives

- #pragma omp ordered execute the loop in the order it would have run serially. Useful if you want ordered output in a parallel region. Never useful for performance.
- #pragma omp master a block that only the master thread (thread 0) executes. Usually, #pragma omp single is better.
- #pragma omp sections execute a list of things in parallel. In OpenMP 3, task directive (later in lecture) is more powerful
- #pragma omp for collapse(n): nested loops scheduled as one big loop.

A bit more on variables

- ▶ We had :
 - #pragma omp ... shared(), private(), and reduction.
- Want private variable to get value from the serial part? Use firstprivate():

```
#include <stdio.h>
int main() {
  int n = 0;
  #pragma omp parallel firstprivate(n)
  {
    #pragma omp for
    for (int i=0;i<100;i++)
        n++;
    printf("My n=%\n",n);
  }
}</pre>
```

A bit more on variables

Private variables are destroyed after parallel region. What if you want the result of a private variable to be preserved? lastprivate():

```
#include <stdio.h>
int main() {
  int n;
  #pragma omp parallel for lastprivate(n)
  for (int i=0;i<100;i++)
    if (i>70) n=i;
  printf("Last n was %\",n);
}
```

Conditional OpenMP

- There is always overhead associated with starting threads, splitting work, etc. Also, some jobs parallelize better than others.
- Sometimes, overhead takes longer than 1 thread would need to do a job - e.g. very small matrix multiplies.
- OpenMP supports conditional parallelization. Add if(condition) to parallel region beginning. So, for small tasks, overhead low, while large tasks remain parallel.

Conditional OpenMP in Action

```
#include <stdio.h>
#include <omp.h>
int main(int argc, char *argv[]) {
  int n = atoi(argv[1]);
  #pragma omp parallel if (n>10)
  #pragma omp single
  printf("have %d
  threads with n=%d\n",
  omp_get_num_threads(),n);
}
```

\$./conditional_if 12
have 8 threads with n=12
\$./conditional_if 9
have 1 threads with n=9

First, pull an integer from the command line. Check to see if it's bigger than a number (in this case, 10). If so, start a parallel region. Otherwise, execute serially.

Controlling # of Threads

- Sometimes you might want more or fewer threads. May even want to change while running.
- Example IBM P6 cluster. Matrix multiply runs fast with twice as many program threads as physical cores (hyperthreading). However, matrix factorizations run slower with more threads.
- omp_set_num_threads(int) sets or changes the number of threads during runtime.

omp_set_num_threads() in action

```
#include "stdio.h"
#include "omp.h"
int main(int argc,char *argv[]){
 //find # of physical cores
 //this is an openmp library routine.
 int max_threads=omp_get_num_procs();
 int n=atoi(argv[1]);
 //set # threads equal to input
 //assuming it's less than
 max_threads if (n<max_threads)
   omp_set_num_threads(n):
 else
   omp_set_num_threads(max_threads);
 #pragma omp parallel
 #pragma omp single
 printf("Running with %d threads for
 n=%d.\n", omp_get_num_threads(),n)
```

We have changed the # of threads during the program. We could always change the number later on in the same code, if we so desired. Note the use of omp_get_num_procs(), a library call to detect the physical number of available processors.

Non-loop construct

OpenMP supports non-loop parallelism as well:

Sections:

```
#pragma omp parallel
 #pragma omp sections
   #pragma omp section
     something to do
   #pragma omp section
     something to do at the
     same time
```

More flexible: tasks

Tasks

- ▶ OpenMP 3.0 supports the #pragma omp task directive.
- A task is a job assigned to a thread. Powerful way of parallelizing non-loop problems.
- Tasks should help omp/mpi hybrid codes one task can do communications, rest of threads keep working.
- Like all omp, tasks must be called from parallel region.
- Raises complication of nested parallelism (what happens if a parallel loop called from parallel loop?).

Tasks: test_task.c

```
#include <stdio.h>
#include <omp.h>
int main(){
 #pragma omp parallel
 #pragma omp single
   printf("hello");
   #pragma omp task
     printf("hello 1 from
     %d.",omp_get_thread_num());
   #pragma omp task
   printf("hello 2 from
   %d.",omp_get_thread_num());
```

Often want to start tasks from as if from serial region. Must be in parallel for tasks to spawn, so #pragma omp parallel followed by #pragma omp single very useful. What would happen w/out #pragma omp single?

Beauty of Tasks

- Some problems naturally fit into tasks that are otherwise hard to parallelize.
- Example (from standard): parallel tree processing.
- ► Each node has left, right pointers, process each sub- pointer with a task.
- ► Look how short the parallel tree is!
- ▶ Works for a variety of non-array structure (linked lists, etc.)

How would you do this problem without tasks?

```
struct node {
 struct node *left:
 struct node *right;
};
extern void process(struct node*);
void traverse(struct node* p) {
 if (p->left)
   #pragma omp task firstprivate(p)
   traverse(p->left);
 if (p->right)
   #pragma omp task firstprivate(p)
   traverse(p->right);
 process(p);
```
